53AUTHOR: Perfilov, N. A.; Solov'yeva, Z. I.; Filov, R. A.; Khlebnikov, G. I.TITLE: Ternary fission of plutonium 19SOURCE: Zhurnal eksper. i teor. fiziki, v. 44, no. 6, 1963, 1832-1836TOPIC-TAGS: ternary fission of plutonium, Alpha-particle energy spectra,
plutonium thermal fission, uranium complex fission

ABSTRACT: The energy spectra of long-range Alpha particles produced in the spontaneous fission of Pu sup 238 and Pu sup 240 and in thermal fission of Pu sup 239 have been studied by the nuclear emulsion method with an aim at comparing both the fission probabilities and the fission Alpha-particle energy spectra of the different isotopes. Electrolytic films of Pu sup 238 and sup 240, containing 78 plus or minus 4 and 450 plus or minus 25 microgram respectively were used in the spontaneous fission test, and Pu sup 239 film irradiated with neutrons from the reactor of FTI AN SSSR was used to obtain the alpha-particle spectrum from thermal-neutron fission. The photographic plates were scanned with a microscope and the resultant histograms were tested for fits to Gaussian distributions with various maxima and half-widths. The spectrum shapes are discussed and compared

Card 1/72

L 13613-63

ACCESSION NR.: AP3003107

with the results for complex uranium fission. Logical reasons for representing the Alpha-particle spectra as Gaussian or near-Gaussian distributions are advanced and agreement in the case of ternary fission of Pu sup 240 is noted with recent work by R. A. Nobles (Phys. Rev. v. 126, 1508 (1962)). "In conclusion, the authors wish to thank V. M. Kulekov for experimental assistance." Orig. art. has: 2 figures, 1 formula, and 2 tables.

TITLE: Some results of the postflight examination of P. I. Belyayev and A. A. Leonov
following their flight on the Voskhod-2 spacecraft [Paper presented at the Conference
on Problems of Space Medicine held in Moscow from 24 to 27 May 1966]

SOURCE: Konferentsiya po problemam kosmicheskoy meditsiny, 1966. Problemy
kosmicheskoy meditsiny. (Problems of space medicine); materialy konferentsii,
Moscow, 1966, 36-37

TOPIC TAGS: space medicine, postflight medical examination, bodily fatigue, body
weight, cardiovascular system, oculocardiac reflex, unconditioned reflex, space
psychology, oxygen consumption, respiration, pulmonary ventilation/Voskhod-2

ABSTRACT: Postflight examinations of the Voskhod-2 crew members, Leonov
and Belyayev, were performed on the third and fourth days after the flight
and again a month later. The cosmonauts complained of light fatigue.
They were found to have hyperemia of the mucosa of the nose and throat
and conjunctivitis of the eyelids and eyeballs. They had lost weight

Card 1/3

L 08268-67

ACC NR: AT6036481

Their pulse showed a certain lability. Pulse frequency rose significantly during mild physical exertions and changes in the position of the body. There was an increase in intraventricular conductivity, an increase in the systolic index (7-11%), and a delay in restoration of hemodynamic indices after physical exercise.

Belyayev's oxygen consumption increased by 23% and Leonov's by 14% as compared with preflight levels. Vital capacity of the lungs diminished by 8-12%, while pulmonary ventilation increased by 51-18%.

Neurological examinations revealed a light tremor of the fingers, a high orthostatic reflex with an absence of pulse reaction to the oculo-cardiac reflex, and an increase in the slow bioelectrical activity of the brain cortex. Psychological tests revealed an increase in distribution and in the middle magnitudes of the duration of the period of sensory motor reaction. Since this was not accompanied by errors, it is possible to assume that the fatigue observed in cosmonauts was a compensatory reaction. Blood and urine examination on the third day after flight did not differ substantially from preflight levels. Biochemical examination uncovered an increase of chlorides, adrenalin, noradrenalin, and 17-oxy corticosteroids in the urine.

Card 2/3

L 08268-67

ACC NR: AT6036481

The observed shifts in physiological indices were short-term and reversible. They indicated the development of moderately marked fatigue in the subjects. Thus, despite the complexity of the flight, the postflight examinations revealed only moderate functional changes in the two cosmonauts. There was no difference in the nature of these changes in the cosmonauts. This indicates a high degree of training and a good neuropsychological and physical preparation for spaceflight.

TITLE: Approximate method for analysis and calculation of principal characteristics of the amplitron

SOURCE: Vsesoyuznaya nauchnaya sessiya, posvyashchennaya Dnyu radio. 22d, 1966. Sektsiya elektroniki. Doklady. Moscow, 1966, 10-19

TOPIC TAGS: amplitron, platinotron, SHF amplifier

ABSTRACT: Distinct from the well-known G. Dombrowskiy method (Trans. IRE, 1959, ED-6, no. 4, 419), a new method is suggested which uses the averaging of SHF potential along the interaction space in the amplitron; this technique permits reducing the amplitron problem to a problem of an induced current in an equivalent magnetron. The space charge is represented as phase-focused converging electron spokes; thanks to the radial SHF-field component, the electrons are focused as they fly toward the anode, which makes the charge density, in the spoke, under dynamic conditions practically constant. A formula for the induced current is developed which is applicable to narrow spokes having any base shape. By using the above space-charge representation and the induced-current relation, formulas are deduced for the amplitron gain, output power, and efficiency; they permit calculating principal characteristics and parameters of the amplitron under normal conditions of its operation. Orig. art. has: 3 figures and 26 formulas.

TITLE: Certain Special Features of the Design of Blast Furnace Nr 5 of the Chelyabinsk Metallurgical Plant (O nekotorykh osobennostyakh konstruktsiy domennoy pechi Nr 5 Chelyabinskogo metallurgicheskogo zavoda)

PERIODICAL: Tekhn.-ekon. byul. Sov. nar. kh-va Chelyab. ekon. adm. r-na, 1958, Nr 2, pp 15-18

ABSTRACT: The cooling system of blast furnace Nr 5 is evaporative. Water consumption for cooling is reduced by an average of 98.75%. Consequently it is possible to use softened water free of matter in suspension and scale-formers. The blast-furnace coolers, and the stove hot-blast and cut-off valves are being re-equipped for evaporative cooling. The overall economic effect of the utilization of evaporative cooling will be about 1.5 to 2.0 million rubles per year.

The relation of soil protein and organic nitrogen as a sanitary index of soils at populated points. N. I. Klibnikov, *Gigiena i Sanit.* 1951, No. 4, 14-19. — The ratio of "soil protein N to the org. N," called the "sanitary no.," is an index of the extent of contamination of the soil. The ratios below 0.7 indicate heavy contamination, 0.7-0.83 moderate contamination, 0.85-0.98 slight contamination, over 0.98 almost no contamination. Considerable exptl. material is presented to support the principle.

Orig Pub : Gigiyena i sanitariya, 1957, No. 31-35 (res. Eng.)

Abstract : A study was made of the influence of non-vegetative and vegetative irrigation of podzolic sandy and loam soils by sewage waters (clarified and sedimented) on the sanitary condition of the soil and the vegetables cultivated in it. The sanitary state of the soil and vegetables was determined by a coli index and by the number of eggs of the helminths, and a sanitary count was also done on the soil. In the vegetative period accompanied by the use of clarified

Electron devices (Elektronnyye pribory) Moscow, Izd-vo :Svyaz'', 1966, 615 p. illus.,
biblio. Textbook for students at electrotechnical institutes of communications.
25,000 copies printed.

semiconductor

TOPIC TAGS: electron tube, semiconductor theory, diode, transistor, cold cathode
tube

PURPOSE AND COVERAGE: The book was written for use in courses on electronic devices
at electrotechnical communications institutes. The operational principles, charac-
teristics, parameters, structures, and schematics of electron devices in communica-
tions engineering are covered. Current electronic equipment is stressed. Part Two
on semiconductor devices has been considerably expanded.

TABLE OF CONTENTS:

Foreword -- 3

Introduction -- 4

Part I. Electric Vacuum Devices

Ch. I. General information on electron tubes -- 11

Card 1/6

UDC: 621.389(075.8)

ACC NR: AM6021847

- 1. Principle of electron tube operation -- 11
- 2. Electrodes of low-power lf and hf electron tubes -- 36
- Ch. II. Electron Tube Operation with Constant Voltages at the Electrodes -- 54
 - 1. Diode -- 54
 - 2. Triode -- 59
 - 3. Pentode -- 80
 - 4. Plate current characteristic equations -- 93
- Ch. III. Electron Tube Operation with Variable Voltages at the Electrodes (quasi-stable regime) -- 110
 - 1. Methods of graphically calculating the plate current -- 110
 - 2. Static and dynamic parameters -- 125
 - 3. Electron tube noise -- 145
 - 4. Control grid negative current -- 156
 - 5. Structure of electron tubes and their application -- 160
- Ch. IV. Special Electron Tubes -- 179
 - 1. Beam tetrode -- 179
 - 2. Wide-band amplifier tubes -- 185
 - 3. Heptode -- 190
 - 4. Cathode-ray tubes -- 199
 - 5. Electron-optical indicator -- 202
- Ch. V. Power Electron Tube -- 204
 - 1. Characteristics and parameters -- 204
 - 2. Power tube electrodes -- 212

Card 2/6

Ch. VI. Operation of UHF Electron Tubes -- 225

1. Diodes -- 225
2. Multi-electrode tubes -- 237
3. Pulse tubes -- 255
4. UHF tube designs -- 258

Ch. VII. Electron-Beam Tubes -- 270

1. Elements of electron optics -- 270
2. Oscillograph -- 283
3. TV picture tubes -- 298
4. Screen -- 304
5. Electron-ray switches -- 307

6. Storage tubes -- 311

Ch. VIII. UHF Electron Tubes -- 314

1. Klystrons -- 314
2. Devices with uninterrupted interaction -- 339
3. Travelling wave tube (type O) -- 356
4. Backward wave tube -- 363
5. Devices with transverse magnetic field (type M) -- 365
6. Magnetrons -- 370
7. Prospects of UHF tube development -- 382

Part II. Semiconductor Devices

Card 3/6

ACC NR: AM6021847

Ch. IX. Electric Properties of Semiconductors -- 393

1. Basic semiconductor materials -- 393
2. Carrier charge concentration in a natural semiconductor -- 393
3. Carrier charge concentration in an N-type semiconductor -- 398
4. Carrier charge concentration in a P-type semiconductor -- 400
5. Conductivity of semiconductors -- 401
6. Carrier charge injection -- 404
7. Current in a semiconductor -- 406

Ch. X. Semiconductor Diodes -- 408

1. Operation of a semiconductor diode at a constant voltage -- 408
2. Operation of a semiconductor diode at a variable voltage -- 423
3. Limiting parameters of a semiconductor diode -- 432
4. Design, types, and use of semiconductor diodes -- 433

Ch. XI. Transistors -- 446

1. Transistor operation at constant voltage -- 446
2. Transistor characteristics -- 460
3. Transistor operation at a variable voltage (quasi-static regime) -- 476
4. Dynamic parameters at low frequencies -- 483
5. Transistor operation at high frequencies (dynamic regime) -- 495
6. Noise in semiconductor devices -- 503
7. Limiting parameters of a transistor -- 506
8. Transistor designs, types, and use -- 508
9. Prospects of semiconductor device development -- 515

New composite photocathodes. N. S. Khel'mikov and N. S. Zaitsev. *J. Tech. Phys.* (USSR), R.P.V., 47-62 (1955).—Sb-Cs, Bi-Cs and Sb-Bi cathodes, both untreated and sensitized by air, were investigated. The sensitivity of these cathodes may be 5 times as high as that of Ag-CuO-Ca cathode; it is almost const. over their whole surface, and slowly decreases when the intensity of irradiation increases. The photocathode current either will only increase with applied voltage or first increases and then more or less suddenly drops (no satn. is observed). The plateau current strength reaches 4×10^{-9} amp/lumen. Special experiments show that this unusual voltage-current curve is not due to a secondary emission. The cathode shows no fatigue for 1 hr.; its sensitivity is not impaired by cooling to -80° . The elec. resistance of an Sb layer increases a thousandfold in the course of a treatment with Cs; its photoelec. sensitivity increases to a const. value which is not affected by a surplus of Cs. Both these effects as well as the properties of the cathode obtained point to the assumption that the cathodes consist of a salt-like compd. of Cs and Sb which may contain some free Cs and is a semiconductor. Electrons are produced in the whole thickness of the cathode. J. J. Bikerman

31. ANTIMONY-CARIUM PHOTOCELLS.—N. S. Khlebnikov. (*Izvestiya Elektrofizm, Nauk, Toks.*, No. 12, 1940, pp. 63-70.)

A general survey is given of the properties of the Sb-Cu photocells. Their physical structure is discussed and spectral as well as volt/ampere characteristics are plotted for photocells in which the cathode is deposited (a) directly on the glass envelope (Fig. 2a) and (b) on a conducting base, usually silver (Fig. 2b). The fatigue of the cells is also considered and curves are plotted (Fig. 3) giving a comparison between this type of cell and the Cu₂O-Ag type. Among other advantages of the Sb-Cu type over the other is the possibility it provides of obtaining a one-colour reproduction of a multi-coloured image. This is illustrated by Fig. 7, in which one-colour reproductions of multi-coloured strips, as obtained respectively with the two types of cell, are shown.

The chemical composition of the antimony-caesium layer, N. S. Khlebnikov. *J. Tech. Phys. (U.S.S.R.)* 17, 833-40 (1947) (in Russian).—Direct analysis of Sb-Cs photocathode layers by leaching with H₂O, titrating CsOH in the mixture and detg. Sb in the residue (e.g., colorimetrically with pyridine) gives erroneous results owing to soln. of Sb in H₂O; Sb condensed from vapor was dissolved in dstd. H₂O completely in about 4 hrs. at room temp. To ascertain the compn. of the photosensitive layer, the amt. of Sb introduced into the cell by evapn. from a Ni wire carrier was detd. directly by weighing the wire before and after the evapn. The Sb layer was then treated with Cs vapor supplied by a CsCl + Ca source until max. sensitivity was reached. In the layer thus formed, Cs was detd. by leaching with H₂O and titration. The compn. was found to correspond to SbCs, with an excess of Cs of about 10 atom % over the stoichiometric ratio. N. Thon

TITLE: Photo-electron and Electron Multipliers (A Review)
(Fotoelektronnye i elektronnye umnozhiteli (Obzor))

PERIODICAL: Pribory i Tekhnika Eksperimenta, 1957, No.6,
pp. 6 - 18 (USSR).

ABSTRACT: The review covers the properties and working conditions of multipliers used for measuring weak light sources and short light pulses produced in the USSR. First working photo-electron multipliers were produced by Kubetskiy (Ref.1) in 1933. This tube was introduced without any substantial changes by RCA in 1934-1935. Kubetskiy anticipated most of the other authors, as can be seen from Ref.2. In the forties, it became obvious that photo-electron multipliers can be very useful and convenient in the measurement of very weak light sources, e.g. in spectroscopy and astronomy. A new stage in the development of these multipliers began in 1947 when Kallman (Ref.4) showed that, in conjunction with a phosphor, electron multipliers can be used as detectors of radio-activity. Applications to nuclear physics soon followed. Such multipliers have three important properties, namely, high amplification (up to Card 1/3 10^8 - 10^9), very small inertia and proportionality between the

Photo-electron and Electron Multipliers (A Review)

120-6-2/36

input and output signals over a wide range of inputs.

a) Multipliers used in nuclear physics. Table 1 gives complete data for 14 multipliers used in scintillation counters. The photocathode diameters range from 15 to 190 mm and the number of dynodes from 9 to 13. Both focussed and Venetian blind type are produced. Amplification factors range from 5×10^4 to 10^7 ,

and rise times from 10^{-8} to 5×10^{-9} secs.

b) multipliers used for weak light sources. Characteristics of 6 such multipliers are given fully in Table 2. The sensitive areas range from $5 \times 5 \text{ mm}^2$ to $5 \times 16 \text{ mm}^2$. Two multipliers having sensitive elements of diameter 15 mm are also given. Sb-Cs, Cs-O-Ag and Sb-Cs photocathodes are employed. Spectral regions covered lie between 2 000 and 10 000 Å.

c) Electron multipliers. The first practical use of the secondary electron emission multiplier without a photocathode was described by Allen (Ref.13). Such multipliers can be used for counting positive ions in mass-spectrometers. In the Soviet Union analogous work was carried out by Livshits (Ref.16). The present authors have investigated various multiplier systems as well as the following alloys for dynodes: Cu-Be, Cu-Mg,

Card2/3 Cu-Al-Mg, Al-Mg-Si. The latter alloy was finally chosen as the

Photo-electron and Electron Multipliers (A Review).

120-6-2/36

most convenient technologically. It is pointed out that it would be very interesting to compare Soviet multipliers with foreign. Unfortunately, there is almost a total absence of foreign multipliers in the Soviet Union.

There are 11 figures, 2 tables and 17 references, 12 of which are Slavic.

"New Types of Photo-electron Multipliers"

A conference on Electron and Photo-electron Multipliers; Radiotekhnika i Elektronika, 1957, Vol. II, No. 12, pp. 1552 - 1557 (USSR)

Abst: A conference took place in Moscow during February 28 and March 6, 1957 and was attended by scientists and engineers from Moscow, Leningrad, Kiev and other centres of the Soviet Union. Altogether, 28 papers were read and discussed.

AUTHOR: Khlebnikov, N. S.

48-1-15/20

TITLE: New Photoelectron-Multipliers (Novyye fotoelektronnyye umnozhiteli).

PERIODICAL: Izvestiya AN SSSR Seriya Fizicheskaya, 1959, Vol. 22,
Nr 1, pp. 70 - 77 (USSR)

ABSTRACT The investigation of the properties of the $\Phi\gamma$ -19 which are also described here served as a starting point for the development of new photoelectron-multipliers. The production of photoelectron-multipliers (PV) better corresponding to the requirements of nuclear physics than the $\Phi\gamma$ -19 is needed. The production of a satisfactory spectrometric multiplier, i.e. of a photoelectron-multiplier with a good amplitude-dissolving-power was considered the most important task. The investigations were made with about 100 $\Phi\gamma$ -19 of current production. The results of the investigations were used by the authors as the basis for some modifications at the input of the device. Besides, problems were raised in this connection which referred to a more expedient construction and to a number of processes in the production of device. The call for the pairing of the front-photocathode with the dynode-system was fundamental, namely the selection of a dynode-system which may easily be combined with a front-

Card 1/3

New Photoelectron-Multipliers.

48-1-15/20

photocathode. Investigations showed that the solution found in this respect is inexpedient in the $\Phi\gamma Y-19$ in the elaboration of quality-PV for scintillation-counters. The necessity of using additional lenses at the input also became evident. The investigation for stability showed that most of the devices are unstable. - It is shown that in the case that the focusing of the flow of electrons from the cathode is sufficiently sharp (for this additional electron-lenses at the input are necessary) all demands made on the device at the input to the spectrometric PV are fulfilled. Taking into account that for the purpose of obtaining PV working more stably, it is necessary to obtain other dynode-materials beside the Sb-Cs-layers, Ye. S. Shpichenetskiy and I. L. Rogel'berg tested some special alloys in the "Gibro-tsvetmetobrabortka"-Institute and finally selected an aluminum-magnesium alloy as the most convenient one in the technological respect. The first spectrometric PV was given the laboratory-mark 1 C. The establishment of the input guarantees the spectrometric properties of every PV which also corresponds to the other fundamental properties - quantum yield at the photocathode, uniformity of sensitivity, amplification. The same results ($\sim 100\%$ collection of electrons) were also obtained in all PV of the type 1 E. The multiplier with a higher disolving power with respect to time was given the mark 1 B. A dynode-system

Card 2/3

New Photoelectron-Multipliers.

48-1-15/20

of a circular type was used here. This system may be well combined with a front-photocathode. The dissolving power with respect to time lies in the domain $(1,5 \pm 3) \cdot 10^{-9}$ sec. Type 2G (diameter of the photocathode 150 mm) and 2 M (diameter of the photocathode 27 mm) were directly developed from this group of multipliers. The ~~arr~~reaching tests of types 1 G, 1G, and 1 B showed good results. The further works will follow the following directions: 1) Mastering of the new dynode-system of the circular type with a large number of dynodes, 2) elaboration of a new chronological system of a linear type with ring-shaped dynodes and 3) elaboration of chronological PV with a large photocathode-surface. The following persons actively participated in working out the new types: A. Ye. Melamid, Ye. P. Yurlova, V. I. Bogatyrev, A. M. Potapov, G. E. Levin, Yu. A. Timoshenko, M. F. Adamovich, V. F. Ivanov. There are 10 figures, 3 tables and 2 references, 1 of which is Slavic.

TITLE: Energy and Angular Distributions of the Photo-electrons
from Complex Cathodes (O raspredelenii fotoelektronov
po energiyam i uglam vlyeta dlya slozhnykh katodov)

PERIODICAL: Radiotekhnika i elektronika, 1959, Vol 4, Nr 6,
pp 1008 - 1017 (USSR)

ABSTRACT: The investigation reported in the article was carried
out during 1950 - 1953 and its aim was to obtain the
data necessary for the design of an electron-optical
system employing complex photo cathodes. The results
obtained by the authors and their interpretation differ
from those obtained by later investigators (Refs 1-6).
The experiments were carried out by employing a
"sectionalised" spherical condenser having an external
diameter of 100 mm (Figure 1). The experimental tube
containing a spherical condenser was in the form illustrated
in Figure 2. The experimental results are shown in
Figures 3-11. Figure 3 illustrates the maximum energy of
the photo-electrons as a function of the quantum energy
 $h\nu$ for two tubes with spherical cathodes ; Curve 1

Card1/4

SCV/109-4-6-14/27

Energy and Angular Distributions of the Photo-electrons from
Complex Cathodes

refers to an antimony-caesium cathode, while Curve 2 was taken with an oxygen-silver-caesium cathode. The slope of the curves gives the average value of the Planck constant. Figure 4 shows that, for both the above cathodes, the saturation points in the current curves changed stepwise during the transition from long to short waves. The energy distribution of the photo-electrons in an antimony-caesium cathode, deposited on a platinum-coated glass sphere, is illustrated in Figure 5; the curves were taken for the wavelengths ranging from 6200 - 2537 Å. The angular distribution of the photo-electrons is illustrated in Figures 7, 8 and 9; the curves marked '1' were taken with a forward illumination, while the curves marked '2' were measured with backward illuminations. Figure 11 shows the electron energy distribution of an oxygen-silver-caesium cathode for the wavelengths ranging from 8000 - 2848 Å. The above experimental results are employed to explain the energy structure of the photo cathodes and to interpret the

Card2/4

SOV/109-4-6-14/27

Energy and Angular Distributions of the Photo-electrons from
Complex Cathodes

process of production and movement of the photo-electrons in the emissive layer. In particular, the experiments show that the angular distribution of the photo-electrons is axially symmetrical and consists of two components: 1) a component having a maximum in the direction normal to the surface and, 2) a component having a maximum at a comparatively large angle. As regards the energy structures of an antimony-caesium cathode, the authors' results indicate that the Burton model (Ref 15) is incorrect. The authors express their gratitude to Ye.P. Turlova for preparing the experimental equipment. Note from the editor: the above article produced a number of criticisms (from various sources) relating to the method of the measurements and the interpretation of the experimental results. However, in view of the novelty

Card3/4

Energy and Angular Distributions of the Photo-electrons from
Complex Cathodes

of the results obtained, the editorial board decided to
publish the paper. There are 13 figures and
17 references, of which 7 are English and 10 Soviet;
one of the Soviet references is translated from English.

SOURCE: US national, and possibly foreign, scientific and technical publications, and other establishments.

Source is a scientist and technician teacher at a scientific laboratory. Because of his position and his personality, he is on such friendly terms with other staff members, many of whom share with him their correspondence with scientists in the US and in foreign lands.

1. In early April 1957 I met with an English translation of a Soviet paper published in the USSR Academy of Sciences Bulletin, "Tekhnicheskaya Elektronika," No. 12, 1956-1957, 1957. This paper reported a Conference on Electronic and Photoclectron Multiplex Field in Russia, 20 Feb.-Mar. 57. see attached translation.

2. This translation was sent to me by a scientist on the East Coast who is a member of an informal group of government officials and government contractor personnel, that try to keep abreast of important international developments in their fields of scientific interest. My friend circulated this translation with a cover letter that indicated his appraisal of its importance. Since I had his judgment in high regard and have confidence in his capability and reliability, I feel that the translated article deserves attention. His translated letter reads as follows:

"My opinion is prima facie up to some of the major tendencies in US development. These findings I believe are due to a lack of specialized personnel in the field of electron optics, secondary emission and photoclectron emission. One might infer that the Russians are considerably ahead of us in many phases, and that their application of these devices extend well beyond the nuclear physics field and probably relate to military guidance systems, etc., which utilize photoclectron devices."

3. The report on the Russo Conference on the Electron and Photoclectron Multiplex records the contributions of the following Soviet scientists:

TITLE: Leonid Aleksandrovich Kubetskiy (Deceased)

PERIODICAL: Uspekhi fizicheskikh nauk, 1960, Vol. 71, No. 2, pp. 351-353

TEXT: On September 22, 1959, the well-known scientist Leonid Aleksandrovich Kubetskiy died from a serious disease. He was born at Pushkina (Leningrad oblast') on July 25, 1906. Already during his school and university years he was very interested in technical problems, especially in electricity. From 1923 on he attended the LGU (Leningrad State University) and from 1925 on the Politekhnicheskiy institut (Polytechnic Institute). In 1928 he started issuing own scientific papers on electronics under the supervision of Academician V. F. Mitkevich. In 1929 he began scientific research work on electrovacuum apparatus at the Leningradskiy fiziko-tehnicheskiy institut (Leningrad Institute of Physics and Technology). Some of the apparatus constructed at that time are mentioned. In the following years he constructed photoelectronic multipliers of the type $\phi\vartheta Y$ (FEU) which founded his fame and play an

important part in experimental physics. These constructions and the development of photoelectronic multipliers in the USA are described. Later, Kubetskiy studied problems of the application of FEU for various measurements as well as general problems of secondary electronic apparatus for which he was awarded the Stalin Prize in 1950. A. A. Chernyshev and Doctor V. K. Zvorykin are mentioned. There are 1 figure and 9 references: 5 Soviet, 1 German, 2 American, and 1 British.

TITLE: A Photomultiplier Sensitive Down to 1300 Å

PERIODICAL: Pribory i tekhnika eksperimenta, 1961, No. 3,
pp. 129 - 131

TEXT: The shortwave limit of a photomultiplier has been extended by the present authors by the use of a "wavelength-shifter", i.e. the short wavelength radiation is converted into a longer wavelength radiation with the aid of a suitable phosphor. It was found that the best results were obtained with the ZhC-9 (ZhS-9) glass plate, 0.1 mm thick. Fig. 1 shows the spectral characteristics of the photomultiplier Φγ-P5 (FEU-R5) with different materials used for the entrance window. Curve 1 was obtained with "optical glass No. 23" and the R5 photomultiplier; Curve 2 was obtained with a 1 mm thick, high-quality uviol glass and an Φγ-P3 (FEU-R3) multiplier and curve 3 was obtained with the ZhS-9 glass (0.1 mm thick) attached with Canada balsam to the

R5 envelope. Curve 3 could not be extended at the time to below 2 030 Å owing to lack of a suitable monochromator. However, there is evidence showing that the sensitivity remains quite appreciable down to 1 500 Å. The present authors' recent measurements, using a vacuum monochromator, have yielded the curve shown in Fig. 2. Fig. 4 shows the light output of the ZhS-9 glass as a function of thickness (mm). There are 4 figures and 1 table.

TITLE: Electron multiplier with an axially symmetrical input
window of 24 cm² area

PERIODICAL: Prihory i tekhnika eksperimenta, 1961, No.3, pp.157-158

TEXT: For recording wide beams of recoil nuclei, electron multipliers are required with an as large as possible area of the cathode from which the recorded particles eject electrons. Fig.1 shows a sketch of the electron multiplier. In this paper an electron multiplier is described, the cathode of which is in the shape of a hemisphere of 60 mm diameter with a central opening of 10 mm diameter. Along the axis a short 6 mm diameter cylinder is placed which is electrically connected with the first dynode. In the gap between the cylinder and the edges of the cathode opening, a ring, with welded on 0.15 mm diameter tungsten wires which are located along the generating lines of the 8 mm diameter cylindrical surface inside the cathode cavity, is fixed onto glass insulators. A potential slightly higher than the cathode

potential is fed to the wire "cylinder" and this produces an additional field that accelerates the electrons which are released from the cathode surface by the primary particles so that the collection of electrons from the peripheral regions of the cathode into the dynode system is considerably improved. To eliminate field distortions in the cathode cavity, the inlet window is covered by a grid to which an independent potential can be fed. Electrons from the cathode, which come into the near-axial region of the cathode with only low energies (due to the accelerating field produced by the wire cylinder), are under the effect of a strong focusing field of the cylinder of the first dynode which collects them onto the active part of its surface. Then follows the ordinary process of multiplication in the dynode system, which has 17 dynodes instead of the usual 11 in the type [C (15) multipliers. The cathode and the dynodes are made of an Al-Mg alloy with an addition of silicon with thicknesses of 0.2 mm and 0.1 to 0.12 mm, respectively. Activation is by alternating heating in vacuum and in an O₂ atmosphere at $t \sim 450^{\circ}\text{C}$ until the required quantity of oxygen (4 to 5 $\mu\text{g}/\text{cm}^2$) is absorbed. An

important advantage of this alloy against other alloys (Ag-Mg, Cu-Mg, Cu-Al-Mg, Cu-Ba) is its reactivation after standing in air (heating in vacuo at 340°C for 30-60 min). The operation of an electron multiplier is as follows: onto each section of the cathode a narrow, 8 mm wide, beam of α -particles is directed and the number of pulses at the output is recorded. Fig.3 shows the focusing curves (N - pulses/sec), taken on displacing the source along the cathode diameter. The half-width of the curve equals 55 mm (which coincides with the diameter of the inlet window) but does not change on changing the efficiency of the recording of the α -particles (curves 1, 2 and 3 were recorded for α -particle recording efficiencies of 100, 45 and 19%, respectively). The best amplitude distribution of the pulses (Fig.4) was obtained for the following operating conditions:

<u>Number of Electrodes</u>	<u>Potential difference, V</u>
Grid-cathode	27 \pm 60
Cathode-wire cylinder	46 \pm 20
Wire cylinder - 1st dynode	380 \pm 100
1st dynode - 2nd dynode	210
Card 3/5 17th dynode - collector	210

2771

E073/E535

The authors also investigated the integral amplitude distribution of the pulses at the output end of the multiplier. Fig.4 shows the integral amplitude distribution of the pulses of the multiplier for α and β particles; the bias on the discriminator (V) is recorded on the abscissa whilst on the ordinate the number of pulses per second N are recorded, the amplitude of which is larger than the bias voltage (top curve - α -particles Po^{210} , bottom curve - γ -particles Co^{60}). The plateau of the counting in the range of small discriminations is characterized by 100% efficiency of recording the α -particles. The background of the electron multiplier for the 70% range of α -particle recording is 2 pulses/sec and in the range of 50% it does not exceed 1.5 pulses/sec. Ye. P. Yurlova and V. I. Ivanov participated in the design and building of the multiplier. There are 4 figures.
